#### Unit: Mathematics

Details

NGSS Standards/MA Curriculum Frameworks (2016): SP5

AP<sup>®</sup> Physics 1 Learning Objectives/Essential Knowledge (2024): N/A

Mastery Objective(s): (Students will be able to ...)

• Use and convert between metric prefixes attached to units.

Success Criteria:

- Conversions between prefixes move the decimal point the correct number of places.
- Conversions between prefixes move the decimal point in the correct direction.
- The results of conversions have the correct answers with the correct units, including the prefixes.

Language Objectives:

• Set up and solve problems relating to the concepts described in this section.

Tier 2 Vocabulary: unit, prefix

#### Notes:

This section is intended to be a brief review. You learned to use the metric system and its prefixes in elementary school. Although you will learn many new S.I. units this year, you are expected to be able to fluently apply any metric prefix to any unit and be able to convert between prefixes in any problem you might encounter throughout the year.

A unit is a specifically defined measurement. Units describe both the type of measurement, and a base amount.

For example, 1 cm and 1 inch are both lengths. They are used to measure the same dimension, but the specific amounts are different. (In fact, 1 inch is exactly 2.54 cm.)

Every measurement is a number multiplied by its units. In algebra, the term "3x" means "3 times x". Similarly, the distance "75 m" means "75 times the distance 1 meter".

The number and the units are <u>both</u> necessary to describe any measurement. You *always* need to write the units. Saying that "12 is the same as 12 g" would be as ridiculous as saying "12 is the same as  $12 \times 3$ ".

The International System (often called the metric system) is a set of units of measurement that is based on natural quantities (on Earth) and powers of 10.

The metric system has 7 fundamental "base" units:

Unit	Quantity
meter (m)	length
kilogram (kg)	mass
second (s)	time
Kelvin (K)	temperature
mole (mol)	amount of substance
ampere (A)	electric current
candela (cd)	intensity of light

All other S.I. units are combinations of one or more of these seven base units.

For example:

**Big Ideas** 

Details

Velocity (speed) is a change in distance over a period of time, which would have units of distance/time (m/s).

Force is a mass subjected to an acceleration. Acceleration has units of distance/time<sup>2</sup> (m/s<sup>2</sup>), and force has units of mass × acceleration. In the metric system this combination of units (kg·m/s<sup>2</sup>) is called a Newton, which means:  $1 N \equiv 1 \text{ kg·m/s}^2$ 

(The symbol " $\equiv$ " means "is identical to," whereas the symbol "=" means "is equivalent to".)

The S.I. base units are calculated from these seven definitions, after converting the derived units (joule, coulomb, hertz, lumen and watt) into the seven base units (second, meter, kilogram, ampere, kelvin, mole and candela).

Big Ideas Details

### Prefixes

The metric system uses prefixes to indicate multiplying a unit by a power of ten. Prefixes are defined for powers of ten from  $10^{-30}$  to  $10^{30}$ :

	Symbol	Prefix		Factor
	Q	quetta	1030	1 000 000 000 000 000 000 000 000 000 0
	R	ronna	10 <sup>27</sup>	$1\ 000\ 000\ 000\ 000\ 000\ 000\ 000\ 0$
$\wedge$	Y	yotta	1024	1 000 000 000 000 000 000 000 000
	Z	zeta	1021	1 000 000 000 000 000 000 000
个 丶	Е	exa	1018	1 000 000 000 000 000 000
	Р	peta	1015	1 000 000 000 000 000
	Т	tera	1012	1 000 000 000 000
£ ₹	G	giga	10 <sup>9</sup>	1 000 000 000
e Le	М	mega	10 <sup>6</sup>	1 000 000
the	k	kilo	10 <sup>3</sup>	1 000
to to	h	hecto	10 <sup>2</sup>	100
oint ai r	da	deca	10 <sup>1</sup>	10
Move Decimal Point to the Left	—		10 <sup>0</sup>	1
ini	d	deci	10-1	0.1
Dec	с	centi	10-2	0.01
l e v	m	milli	10-3	0.001
Mo	μ	micro	10-6	0.000 001
	n	nano	10 <sup>-9</sup>	0.000 000 001
<b>↑</b> √	р	pico	10-12	0.000 000 000 001
<b>∧</b> √	f	femto	10-15	0.000 000 000 000 001
	а	atto	10 <sup>-18</sup>	0.000 000 000 000 000 001
<b>↑</b> √	z	zepto	10-21	$0.000\ 000\ 000\ 000\ 000\ 000\ 001$
	у	yocto	10-24	0.000 000 000 000 000 000 000 001
	r	ronto	10 <sup>-27</sup>	$0.000\ 000\ 000\ 000\ 000\ 000\ 000\ 00$
	q	quecto	10-30	0.000 000 000 000 000 000 000 000 000 0

Note that some of the prefixes skip by a factor of 10 and others skip by a factor of 10<sup>3</sup>. This means *you can't just count the steps in the table—you have to actually look at the exponents*.

The most commonly used prefixes are:

• centi (c) =  $10^{-2} = \frac{1}{100} = 0.01$ 

- mega (M) =  $10^6 = 1\,000\,000$  milli (m) =  $10^{-3} = \frac{1}{1\,000} = 0.001$
- kilo (k) = 10<sup>3</sup> = 1000
- micro ( $\mu$ ) = 10<sup>-6</sup> =  $\frac{1}{1\,000\,000}$  = 0.000001
- Any metric prefix is allowed with any metric unit. For example, "35 cm" means " $35 \times c \times m$ " or "(35)( $\frac{1}{100}$ )(m)". If you multiply this out, you get 0.35 m.

Note that some units have two-letter abbreviations. *E.g.,* the unit symbol for pascal (a unit of pressure) is (Pa). Standard atmospheric pressure is 101325 Pa. This same number could be written as 101.325 kPa or 0.101325 MPa.

	The International System of Units Page: 110
Big Ideas	Details Unit: Mathematics
	There is a popular geek joke based on the ancient Greek heroine Helen of Troy. She was said to have been the most beautiful woman in the world, and she was an inspiration to the entire Trojan fleet. She was described as having "the face that launched a thousand ships." Therefore a milliHelen must be the amount of beauty required to launch one ship.
	Conversions
	If you need to convert from one prefix to another, simply move the decimal point.
	<ul> <li>Use the starting and ending powers of ten to determine the number of places to move the decimal point.</li> </ul>
	• When you convert, the actual measurement needs to stay the same. This means that if the prefix gets larger, the number needs to get smaller (move the decimal point to the left), and if the prefix gets smaller, the number needs to get larger (move the decimal point to the right).
	Definitions
	In order to have measurements be the same everywhere in the universe, any system of measurement needs to be based on some defined values. As of May 2019, instead of basing units on physical objects or laboratory measurements, all S.I. units are defined by specifying exact values for certain fundamental constants:
	• The Planck constant, <i>h</i> , is exactly $6.62607015 \times 10^{-34}$ J·s
	• The elementary charge, $e_r$ is exactly 1.602 176 634 × 10 <sup>-19</sup> C
	• The Boltzmann constant, k, is exactly 1.380 649 × $10^{-23}$ J·K <sup>-1</sup>
	• The Avogadro constant, $N_A$ , is exactly 6.022 140 76 × 10 <sup>23</sup> mol <sup>-1</sup>
	<ul> <li>The speed of light, c, is exactly 299 792 458 m·s<sup>-1</sup></li> </ul>
	<ul> <li>The ground state hyperfine splitting frequency of the caesium-133 atom, Δv(<sup>133</sup>Cs)<sub>hfs</sub>, is exactly 9 192 631 770 Hz</li> </ul>
	• The luminous efficacy, $K_{cd}$ , of monochromatic radiation of frequency 540 × 10 <sup>12</sup> Hz is exactly 683 lm·W <sup>-1</sup>
	The exact value of each of the base units is calculated from combinations of these fundamental constants, and every derived unit is calculated from combinations of base units.

### The MKS vs. cgs Systems

Because physics heavily involves units that are derived from other units, it is important to make sure that all quantities are expressed in the appropriate units before applying formulas. (This is how we get around having to do factor-label unitcancelling conversions—like you learned in chemistry—for every single physics problem.)

There are two measurement systems commonly used in physics. In the MKS, or "meter-kilogram-second" system, units are derived from the S.I. units of meters, kilograms, seconds, moles, Kelvins, amperes, and candelas. In the cgs, or "centimeter-gram-second" system, units are derived from the units of centimeters, grams, seconds, moles, Kelvins, amperes, and candelas. The following table shows some examples:

Quantity	MKS Unit	Base Units Equivalent	cgs Unit	Base Units Equivalent
force	newton (N)	$\frac{\text{kg·m}}{\text{s}^2}$	dyne (dyn)	$\frac{g \cdot cm}{s^2}$
energy	joule (J)	$\frac{\text{kg·m}^2}{\text{s}^2}$	erg	$\frac{\mathbf{g}\cdot\mathbf{cm}^2}{\mathbf{s}^2}$
magnetic flux density	tesla (T)	$\frac{N}{A}$ , $\frac{kg \cdot m}{A \cdot s^2}$	gauss (G)	$\frac{0.1\text{dyn}}{\text{A}},\frac{0.1\text{g}{\cdot}\text{cm}}{\text{A}{\cdot}\text{s}^2}$

In general, because 1 kg = 1000 g and 1 m = 100 cm, each MKS unit is 100000 times the value of its corresponding cgs unit.

In this class, we will use exclusively MKS units. This means you have to learn only one set of derived units. However, you can see the importance, when you solve physics problems, of making sure all of the quantities are in MKS units before you plug them into a formula!
